OVERVIEW

During 2019, 114 tuberculosis (TB) cases were reported to Alameda County (excluding the City of Berkeley). The 2019 TB case rate in Alameda County was 7.4 cases per 100,000 residents, a 26% decrease from the 2018 rate. The 2019 rate ranks seventh among all jurisdictions in California and is 0.5-fold higher than the California state rate of 5.3 cases per 100,000 residents. Compared to other Bay Area jurisdictions, the Alameda County rate ranks lower than San Francisco (13.4 per 100,000), Santa Mateo (8.5 per 100,000), and San Clara (8.4 per 100,000), but higher than Solano (7.0 per 100,000), and Contra Costa (5.0 per 100,000) counties.

PATIENT DEMOGRAPHICS

Similar to previous years, a majority of TB cases were male (60.5%). During 2019, the largest proportion of TB cases occurred among adults 65 years old and older (37.7%), and the lowest proportions occurred among children 0 to 4 years old (0.0%) (Table 1).

The majority of 2019 TB cases (98.2%) occurred among non-White residents (Table 1). From 2017 to 2019, Asian/Pacific Islander (API) residents in Alameda County had an average annual case rate of 20.7 cases per 100,000 residents, followed by Hispanic residents at 4.4 cases per 100,000 residents.

During 2019, 91.2% of TB cases were born outside of the U.S. (Table 1). The most frequent birthplaces outside of the U.S. remain the Philippines, India, China, Mexico, and Vietnam (Figure 2). The 2017-2019 average annual case rate for cases born outside of the U.S. was 23.3 per 100,000, almost 18 times the rate for cases born in the U.S. (1.3 per 100,000). For 2019 cases born outside of the U.S., 64.4% had resided in the U.S for 10 years or more before being diagnosed with TB.

The largest proportion of 2019 TB cases occurred among residents of Oakland (28.9%), Fremont (22.8%) and Hayward (14.0%). Five-year average rates were highest in Downtown and East Oakland, and South Fremont (over twice the five-year county average of 8.6 per 100,000) (Figure 3).
CLINICAL CHARACTERISTICS

Of all 2019 TB cases, 75.4% had any pulmonary involvement and 24.6% were extrapulmonary only (Table 2). Of all pulmonary cases, a majority (50.0%) were acid-fast bacilli (AFB) smear-negative and 65.1% did not have evidence of cavitary disease on chest radiography. Only 3.5% of 2019 TB cases were co-infected with HIV. The most common comorbidity was diabetes (23.7%).

DRUG RESISTANCE

Fewer drug-resistant isolates were identified among culture-positive cases during 2019 when compared to 2018 (12.8% vs 20.0%), but a similar to proportions detected during 2015-2017 (12.8% vs. 4.8%-11.5%). During 2019, 12 TB cases were resistant any TB treatment drug, and 9 to at least one first-line treatment drug (isoniazid, rifampin, ethambutol or pyrazinamide). Of all TB cases with drug susceptibility tests reported, 6 cases (6.4%) were resistant to isoniazid only, 3 (3.2%) were resistant to pyrazinamide only, and 1 (1.1%) case was resistant to isoniazid and streptomycin. Alameda County had two multidrug resistant TB cases (one resistant to isoniazid, rifampin, pyrazinamide, and ethambutol; and one resistant to isoniazid with susceptibility to rifampin, but had molecular mutations detected that have been associated with multidrug-resistant TB cases).

DIAGNOSTIC TESTING

Among 2019 TB cases with any pulmonary disease, 67.4% received a nucleic acid amplification (NAA) test at diagnosis, a lower proportion than among 2018 cases (73.9%). Similar to 2018, more 2019 cases with positive sputum AFB smears received NAA tests compared to patients with negative sputum AFB smears (80.4% and 89.4%, respectively); a smaller proportion of 2019 cases with negative sputum AFB smears received a NAAT test compared to 2018 (50.0% and 62.3%, respectively).

SUMMARY

TB remains an important public health problem in Alameda County. Preliminary analyses have not identified a specific cause for the reduction in TB cases and rates in Alameda County; however, one possible explanation is that the declines in cases and rates may be due to natural variation that has been observed in previous years. A large proportion of Alameda County TB cases continue to occur among older adults, those born outside of the U.S., and non-U.S.-born cases who have been in the U.S. for 10 years or more before TB diagnosis; all are known risk factors for latent TB infection (LTBI). Reports have also indicated that 80%-85% of all TB cases are due to LTBI reactivation. Therefore, identifying and treating LTBI is a key TB control strategy. TB Control also continues to encourage early diagnosis through the use of NAA tests, as this practice may facilitate earlier TB treatment initiation and reduce disease transmission.
